

JSP TAGS Quiz - Amir

1, `<% Student [] table = (Student []) request.getAttribute("student");%>`

`<% for (int i = 0; i < table.length; i++){ %>`

`<tr>`

`<td><%= table[i].getName() %></td> <td><%=table[i].getAge() %></td>`

`</tr> <%}%>`

2, JSTL is a java standard library of actions in a JSP. Aside from the library full of actions we get by importing JSTL sometimes we might need to use our own user defined custom tag to carry out a specific task. Custom tags are also useful for reusability.

3, The role of the URI attribute in the TLD and taglib directive is to resolve a location the container understands where the TLD file is.

4, Tag handler classes are classes that allow us to extend and use the tag framework in our JSP and allow access to any file within the request, session and application level.

5, each attribute of custom tag in order to set the values into the variable it creates needs a setter and getter attribute methods.

6, Called by the container to invoke a specific tag. The implementation of this method is provided by the tag library developer, and handles all tag processing, body iteration.

7, It outputs the string HI Bob in the console.

8, It means the process of the output of the body should go to the response and not to any other write code we passed in.
